

Chicken Eggs

Conventional vs. Organic

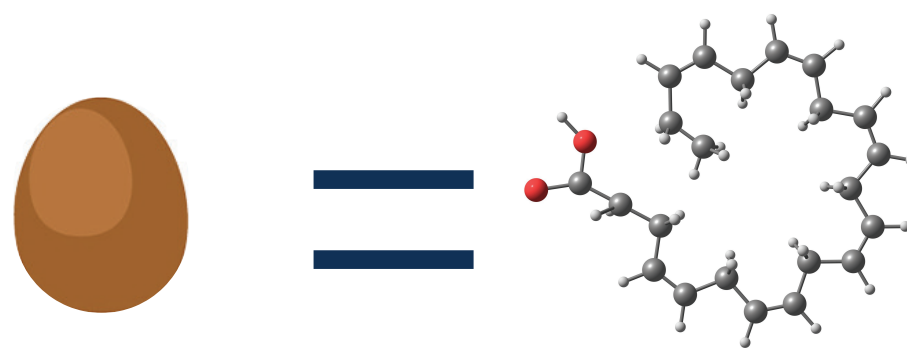

Pastured eggs contain about 208 milligrams of DHA per 100 calories, which is 3.5 as much as in conventional eggs (Mugnai et al., 2014).

**DHA in
1 Pastured Egg**

**DHA found in
3.5 Conventional Eggs**

One large egg provides about 70 Calories, a single egg provides roughly 150 mg of DHA, an amount that is comparable to some seafood.

1 Pastured Egg

150 mg DHA

The chicken feed appears to be the most important factor of egg-nutrient composition.

There are minimal differences between eggs of chickens that received the same feeding regimen but were raised either in cages or free-range (Anderson, 2011).

Supplementing the chicken's diet with vitamin D leads to notable doses of 100–400 IU of vitamin D per egg (Browning & Cowieson, 2014).

Free-range chickens that have regular access to sunlight also produce eggs with minimally higher vitamin D concentrations (Kühn, et al., 2014).
