

Digestive health often becomes a major hurdle when consuming large amounts of a given ingredient or lacking variety throughout the meal prepping process. Within this video, Chris talks about common foods used in meal prepping that often contribute to digestive health issues, what to look for, and how to overcome these potential health risks.

Chris's Key Takeaways

Rice products are easily digested due to their low fiber content.

Potatoes, when overconsumed, can lead to GI issues.

Consume potatoes at the time they are cooked to minimize the development of resistant starches which can make them harder to digest.

Avocados, when overconsumed, can result in IBS-like symptoms.

Although nuts are a great fat to incorporate into a meal plan, they can be easily overconsumed which can lead to GI issues.

Oatmeal is a great contest prep food but, in the off-season, can lead to a loss of appetite and gas when overconsumed.

It is common for those overconsuming wheat products to experience allergy-like symptoms often confused as an allergy itself.

Gluten-free pasta is a good alternative to help minimize the intake levels of wheat proteins.

Dry spices often contain garlic, onion, and pepper which can lead to GI issues.

Sauces, when overconsumed, may contribute to reflux (GERD) and heartburn-like symptoms.

Most digestive issues experienced are often isolated to the individual or are dose dependent.
