

Part IV: Meal Prep Cooking Fish

Cooking fish has both its advantages and disadvantages when meal prepping. Because of individual preferences and shelf life, fish can present challenges when using this protein source throughout prep. In this video, Chris demonstrates how he prepares different types of fish and tips to help maximize taste.

Chris's Key Takeaways

Pan-cooking fish is the fastest way to cook fish.

Cooking salmon with the skin side down will release collagen and protein holding the skin and muscle together, making it easy to pull off.

Because of how delicate fish is and how fast it cooks, monitor it throughout the cooking process to avoid overcooking.

Unconventional flavor combinations such as no-sugar-added ketchup and hot sauce can be used to help mask the fish flavor of salmon.

Because of salmon's higher fat content, it doesn't require cooking spray or oil on the pan to cook.

Cod has very low-fat content and requires oil on the pan to avoid sticking.

Cod should be cooked using medium heat.

Cod, same as salmon, requires an internal temperature of 145°F.

Without using a thermometer, cod is thoroughly cooked when it becomes an opaque white color and easily flakes.

Cod, unlike most protein sources, has a poor yield and shrinks considerably once cooked.
