

- The spotter should regulate the number of total repetitions performed by the athlete prior to the beginning of each set.

- The spotter should stand and maintain a stable, wide-stance body position to increase the maximal safety of the corresponding exercise.

- An experienced spotter delivers adequate and ample support for the client to successfully execute the lift, especially when lifting through the sticking point.

- The spotter is encouraged to spot at the client's wrists instead of the elbows when using dumbbells (i.e., in a dumbbell shoulder press). Spotting at the wrist provides better support for the lifter and prevents the elbows from caving inward.
- During the barbell squat exercise, the spotter should be positioned behind the lifter, and the upper arms should be placed underneath the lifter's armpits. This provides maximum spotting security between the spotter and the lifter.
- Use an additional spotter for exercises when the load surpasses what a single spotter can successfully manage on their own. For example, two spotters will stand on opposite sides of the barbell during a heavy barbell back squat exercise. When and if needed, the spotters will assist the lifter in accomplishing the movements by lifting the ends of the barbell until they are able to complete the exercise.
- Spotters are not recommended to spot machine- or cable-based exercises by placing their hands underneath the weight stack. This increases the risk of injury to the spotter and the lifter.
